Class : M.Sc. Zoology  
Sub : *Assignment file*

Topic → BLAST

(Basic local alignment search tool)

## ★ Summary

- Introduction

- Type of BLAST algorithm

- Special algorithm of BLAST

- How BLAST work?

- Pictorial representation

- Application in medical Biotechnology

- Input/Output of BLAST

- Word searching method • Identification of exact work

- Maximum segment pair alignment
- Use of BLAST

# # Introduction:-

- BLAST stands for Basic local Alignment Search tool.
- BLAST is a program which uses specific scoring matrices (like PAM or BLOSSUM) for performing sequence - similarity searches against a variety of sequences data bases, to give us high-scoring ungapped segments among related sequences.
- Complex - requires multiple steps and many parameters.
- The BLAST algorithm is fast, accurate & web-accessible.
- Is relatively faster than other sequences similarity search tools.
- Provides us with ability to perform analysis by different type of programs.

## # Types of BLAST Algorithm :-

<u>Program</u>	<u>Input</u>	<u>Query search</u>	<u>Database</u>
blastn	DNA	1 →	DNA
blastp	Protein	1 →	Protein
blastx	DNA	6 →	Protein
tblastn	Protein	6 →	DNA
tblastx	DNA	36 →	DNA

## # Types of BLAST Algorithm :-

<u>blastn</u>	- Compares a DNA query sequence against a DNA database, allowing for gaps
<u>blastp</u>	- Compares a protein query sequence against a protein database, allowing for gaps
<u>blastx</u>	- Compares a DNA query sequence translated into six reading frames against a protein database, allowing for gaps

<u>tblastn</u>	Compares a protein query sequence against a DNA database translated into six reading frames, allowing for gaps
<u>tblastx</u>	Compares a DNA query sequence translated into six reading frames against a DNA database translated into six reading frames. <u>tblastx doesn't allow for gaps</u>

## # Special Algorithm of BLAST :-

<u>MEGABLAST</u>	:- For comparison of large sets of <u>long DNA sequences</u>
<u>RPS-BLAST</u>	:- <u>Conserved Domain Detection</u>
<u>BLAST 2 Sequences</u>	:- For performing <u>pair-wise alignments for 2 chosen sequences</u>
<u>Genomic BLAST</u>	:- For alignments against <u>select human, microbial or malarial genomes</u>

PSI-BLAST :- Construct a multiple alignment from matches

PHI-BLAST :- Specify a pattern that hits must match

## # HOW BLAST WORKS ?

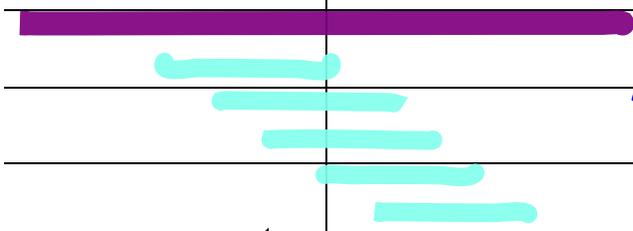

**BLAST** works in following two steps :-

1. BLAST first searches for short regions of a given length (W) called "words" (or substrings) that score at least "T" when compared to the query sequence that align with sequences in the database (target sequences) using a substitution matrix.

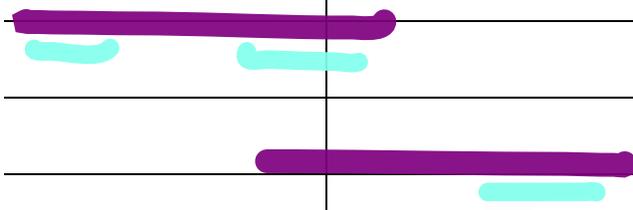

2. For every pair of sequences (query & target) that have a word or words in common, BLAST extends the alignment in both directions to find alignments that score greater (are more similar) than a certain scoring pairs or HSPs; the maximal scoring HSPs are called MSPs.

#

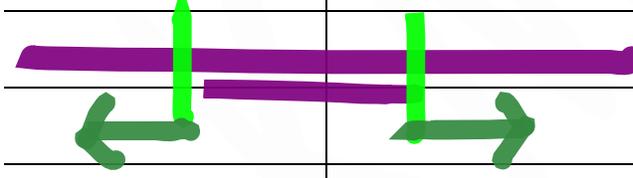

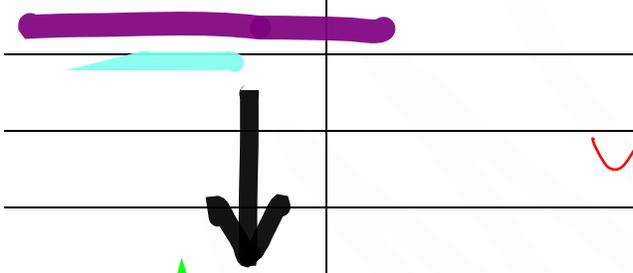

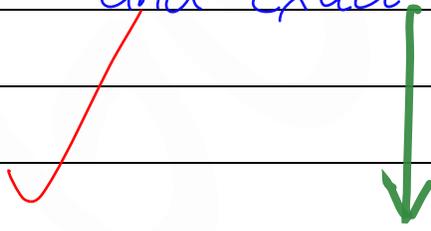

# PICTORIAL REPRESENTATION:-

"Words" (Subsequences of the query seq.)

Query words are compared to the database (target sequences) and exact matches identified

For each word match, alignment is extended in both directions to find alignments that score greater than some threshold (maximal segment pairs, or MSPs)

There are various questions which a BLAST can handle which commonly arises

Now as to see whether this protein has any similarity between other organism we perform a BLAST to understand its importance.

# # Input/Output of BLAST

## → Input :-

- Query sequence  $Q$
- Database of sequences  $DB$
- Minimal score  $S$

## → Output :-

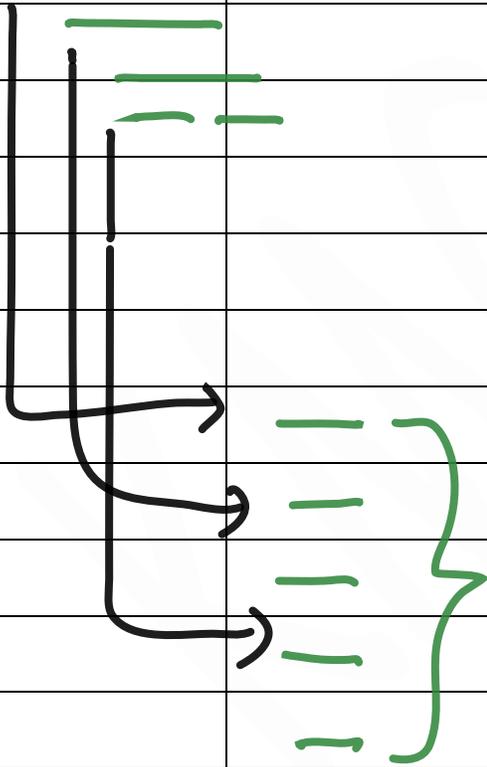

- Sequences from  $DB$  (seq), such that  $Q$  and  $S$  seq. have score  $> S$

# 1. Word searching method

1. For the query, find the list of high scoring words of length

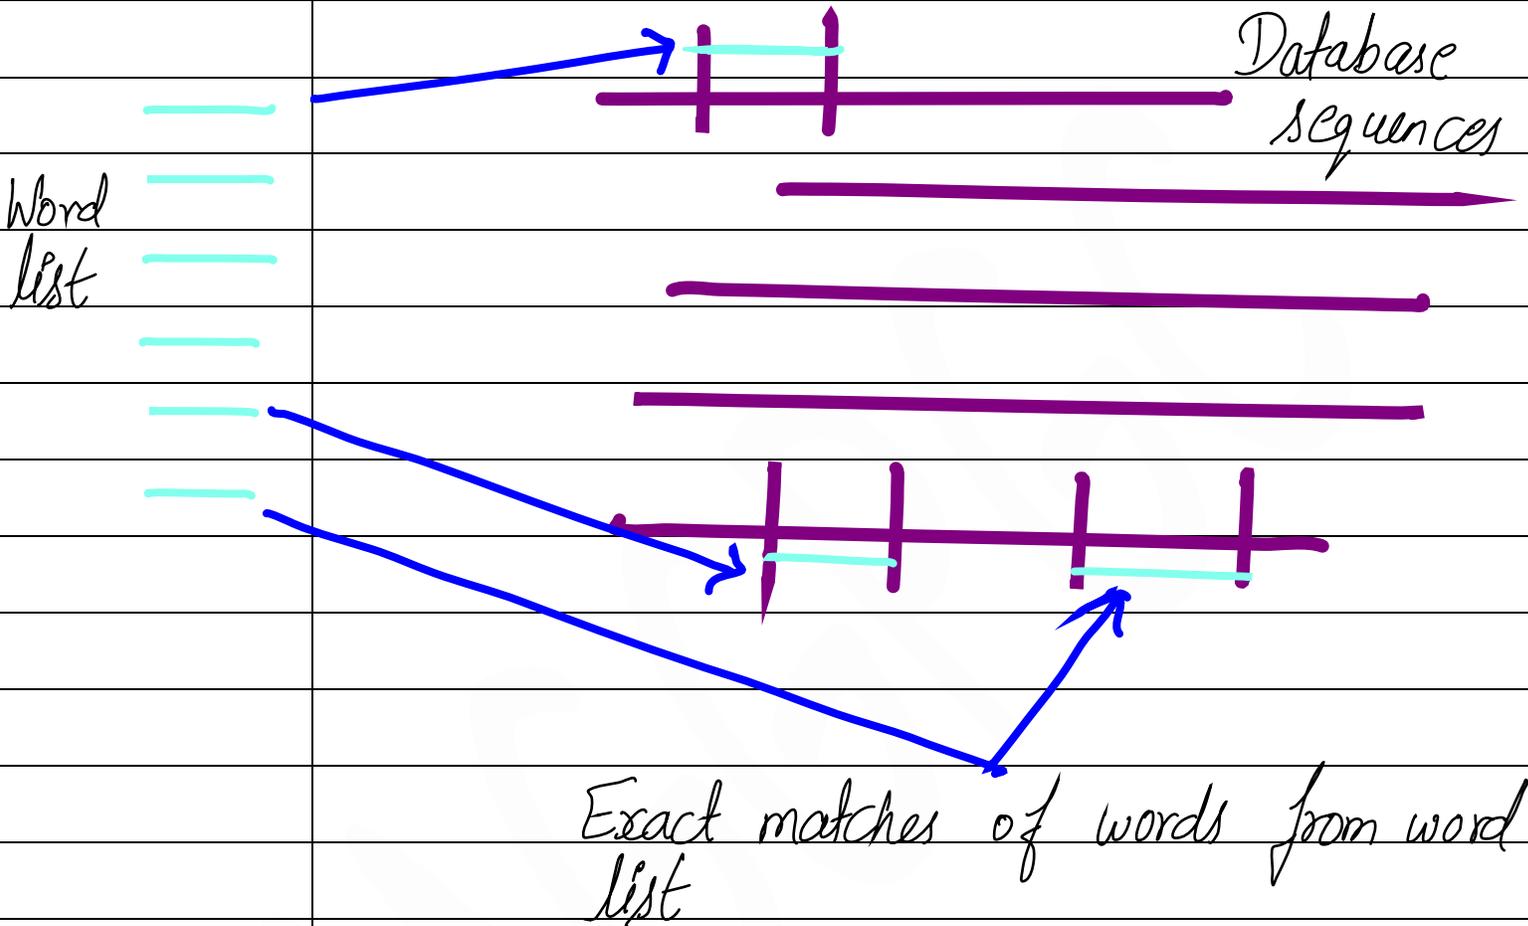

Query sequence of length  $L$

← - - - Maximum of  $L - W + 1$  words (typically  $w = 3$  for proteins)

For each word from the query sequence find the list of words that will score at least  $T$  when scored using a pair-score matrix (e.g. PAM25)

2. Compare the word list to the database & identify exact matches

## 2. Identification of exact word

Word :-

MEAVKKEEISVEDEAVDK

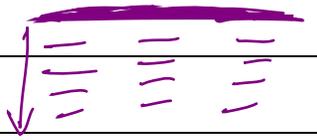

overlapping

MEA  
EAA  
AAV  
AVK  
VKE  
KEE  
EEI  
EIS  
ISV

Break query  
into words

Break data  
base sequences into  
word

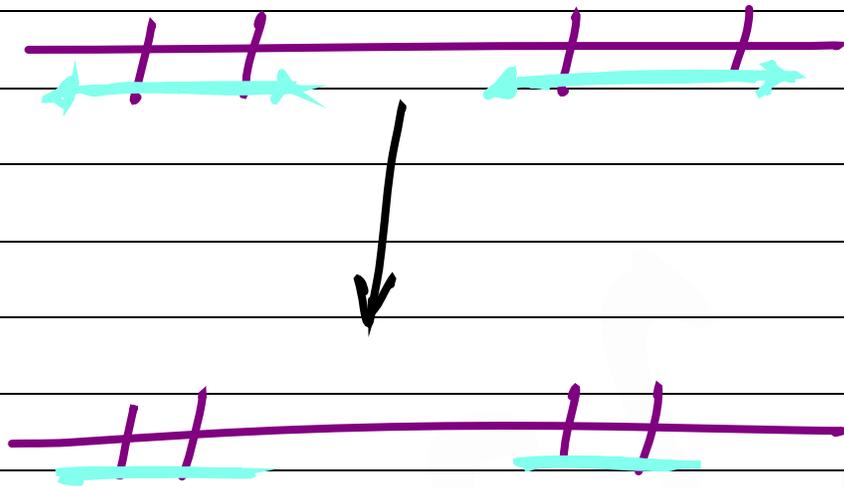

### 3. Maximum segment pair

alignment : Extend hits

one base at a time

For each word match, extend the alignment in both directions to find alignments that score greater than a threshold of value **S**

Maximal segment Pairs (MSPs)

## # Uses of BLAST:-

### -o Identifying species

With the use of BLAST, identify a species. This can be useful, for example, when you are working with a DNA sequence from an unknown species.

## → Locating domains :-

When working with a protein sequences you can input it into BLAST, to locate known domains within the sequence of interest.

## → DNA Mapping :-

When working with a known species, & looking to sequence a gene at an unknown location, BLAST can compare the chromosomal position of the sequence of interest to relevant sequences in the database(s).

## → Comparison :-

When working with genes, BLAST can locate common genes in two related species and can be used to map annotations from one organism to another.
